Fiscal Year:	FY 2017	Task Last Updated:	FY 09/09/2016
PI Name:	Mancinelli, Rocco Ph.D.		
Project Title:	Elucidating The Nitrogen Cycle of Eu:CROPIS (Euglena: Combined Regenerative Org	anic-food Production In Space)
Division Name:	Space Biology		
Program/Discipline:			
Program/Discipline Element/Subdiscipline:	SPACE BIOLOGYCellular and molecular biol	ogy	
Joint Agency Name:		TechPort:	No
Human Research Program Elements:	None		
Human Research Program Risks:	None		
Space Biology Element:	 Cell & Molecular Biology Microbiology 		
Space Biology Cross-Element Discipline:	(1) Reproductive Biology		
Space Biology Special Category:	 (1) Cell Culture (2) Translational (Countermeasure) Potential (3) Bioregenerative Life Support 		
PI Email:	mancinelli@baeri.org	Fax:	FY
PI Organization Type:	NON-PROFIT	Phone:	(650) 604-6165
Organization Name:	Bay Area Environmental Research (BAER) Insti-	tute	
PI Address 1:	Mail Stop 239-4, NASA Ames Research Center		
PI Address 2:

Contact Email:	kevin.y.sato@nasa.gov		
Flight Program:	Small Satellites		
Flight Assignment:	NOTE: End date changed to 9/30/2018 per F. He	rnandez/ARC (Ed., 3/23/17)	
Key Personnel Changes/Previous PI:			
COI Name (Institution):	Hauslage, Jens (DLR (German Aerospace Cent Richter, Peter (Friedrich-Alexander-Universitä	ter)) t - Erlangen, Germany)	
Grant/Contract No.:	Coop Agreement via NNX12AD05A		
Performance Goal No.:			
Performance Goal Text:			

	Editor's Note (12/2/2013): Funding is for Dr. Mancinelli's participation as Co-Investigator on the German Aerospace Center (DLR)'s Eu:CROPIS (Euglena with Combined Regenerative Organic-food Production In Space) mission and the Principal Investigator of the nitrogen cycling portion of the mission, entitled "Elucidating The Nitrogen cycle of Eu:CROPIS (Euglena: Combined Regenerative Organic-food Production In Space)." The objective of the proposed study is to determine the effect of different gravity levels on the nitrogen cycle leveraging experiments to be flown on DLR's Eu:CROPIS mission. This is of importance to NASA because The National Research Council's Plant and Microbial Biology Decadal Survey (2011) states that there is a need for understanding the role of gravity on microbe-microbe interactions and microbe-plant interactions. The research proposed here will do just that. Nitrogen is an essential element for life. It is present in all living systems, occurring in several important molecules including proteins and nucleic acids. Without nitrogen life as we know it could not exits. Thus, the nitrogen cycle is important to supporting life whether it is on Earth, in space, or on other planets or moons. Because only Earth has a 1 x g environment understanding how the nitrogen cycle operates as a function of gravity is key to sustaining life off of Earth.
Task Description:	To change the gravity levels the spacecraft will be maneuvered (by spinning) to produce three different gravity regimes during the courser of the mission. The three gravity regimes will be $0.01 \ge g - 0.1 \ge g$ (essentially microgravity); $0.16 \ge g$ (Moon gravity); and $0.38 \ge g$ (Mars gravity). Each gravity regime will last for six months. Eu:CROPIS will be used in reducing organic waste and in the development of efficient life support systems. Its core element is a microbiological trickling filter of lava rock – the habitat of a multitude of microorganisms that purify and decontaminate water. The development aims at a wet composting system that may be used in closed life support systems such as waste water recovery. A key component of the system is the nitrogen cycle. So, modeling the nitrogen cycle of the system is essential to understanding how the system functions. It will be the first time nitrogen-transformation reactions will be measured as a function of gravity. NASA has an excellent opportunity to participate in the DLR's Eu:CROPIS mission that allows us to obtain data by leveraging their laboratory work and hardware at a fraction of what it would cost if funded/supported solely by NASA.
Rationale for HRP Directed Research	:
	The need for fundamental research to understand the role of gravity on microbe-microbe interactions microbe-plant interactions and microbe human interactions in space is recognized in the National Research Council's Plant and Microbial Biology Decadal Survey (2011) on Biological and Physical Sciences in Space (chapter 4). Through the proposed work, data from the Eu:CROPIS mission will address microbe-microbe and microbe plant interactions through cycling of key nutrients, specifically nitrogen, oxygen, and carbon. Eventually, space travel will require the ability for self-sufficiency. Once mission profiles extend beyond short trips to the lunar surface, the duration of each mission will mean it will no longer remain cost-effective - or indeed feasible - to dispose of all waste and resupply oxygen, water, and food to crew members from Earth. NASA has acknowledged this reality for more than two decades with programs exploring the development of both physicochemical and bioregenerative life support systems. The program on bioregenerative capabilities arose from observations that the only truly long-term, self-sustaining life support system that has a demonstrated stability and efficacy relies upon biological systems for its function; that system is the life support afforded by Earth. Since bioregenerative life support systems are not high on the NASA priority list at this time it was stated in the report: Because international collaborations will be essential to make rapid progress with these aims, NASA should support collaborations, where appropriate, with partners that are already pursuing these goals, such as European scientists
Research Impact/Earth Benefits:	Eu:CROPIS is a clear example that fits in with this statement. It allows NASA to obtain this data at little cost by using the laboratories, the hardware, and the spacecraft paid for by the DLR. The Eu:CROPIS (Euglena: Combined Regenerative Organic-food Production In Space) experiment will test the feasibility and technology in the areas of life support systems and gravitational biological research. The mission offers for the first time the opportunity of analyzing coupled biological life support systems under different levels of gravity (space, moon, Mars) utilizing state-of-the-art methods for image and molecular analysis. It combines the C.R.O.P. system plant gravith water purification system developed at the DLR in Cologne, Germany with the well studied Euglena gracilis space flight system. Euglena gracilis is a motile, photosynthetic, unicellular flagellate living in ponds and lakes. It uses gravity and light as hints to reach and stay in regions of the water column optimal for photosynthesis and gravitaxis). Euglena is considered a 'professional gravi-sensing organism,' a term that was coined by ESA (European Space Agency). In the past 15 years, Euglena has been established as a model organism for studying gravity perception of single cells. A model for gravitaxis was created by the combination of physiological, biochemical, and molecular biological methods. In this context substantial contributions came from microgravity experiments in space.
	 Progress to date Demonstrated Euglena growth on NO3- as well as on NH4+. Significance: Complicates the interpretation of the N-transformation reactions and their rates in the primary payload.
	• Demonstrated Euglena growth on NH4+ produced by cyanobacteria in co-culture in 2 types of media. Significance: Euglena able to grow on NH4+ produced by other organisms (ground control data for potential contaminants in system – the current prototype CROP system is full of cyanobacteria).
	• Colorimetric assays for the various nitrogen species produced variable results leading to the decision to use ion-chromatography for the ground controls and flight experiment. Significance: Changes the hardware, its configuration, as well as mass, power and volume in the payload.
	• Decision finalized to use gas sensors to measure atmospheric gases in the primary payload instead of a gas chromatograph. Significance: Gas sensors are simpler and less prone to error and failure. It also impacts the hardware configuration as well as resulting in a reduction in the mass and power requirements.
	• Using the ion chromatograph we are monitoring the concentration of the ammonium, nitrate, and nitrite in the system as well as net rate of the reactions from a batch of 20% synthetic urine run through the CROP system.
	• Computer simulations of the microbial and nitrogen species changes in the Eu:CROPIS system were refined to better incorporate the data obtained from the CROP portion of the system.

Task Progress:	• We constructed an additional test module that isolates each component of the system (i.e., greenhouse for Euglena, tomato growing section, trickling filter, etc.), such that they can function independently. This module is fitted with gas inlets/outlets and sampling ports so that we can control the atmosphere in the system. This allows us to test each system at various O2 levels in a controlled manner. In the multi-modular test system running without tomatoes the addition of urea needs to be balanced with biomass production. To that end we have modified the system and improved the O2 production rate compared to the data
	obtained, improving the connection filter between the algae tank and the lava-tricking filter. In this improved system when it is flushed with 500 μ l of urea it results in a significant reduction of oxygen but a much shorter time for oxygen recovery (build-up) in the system. Currently, the algae tank seems to be providing sufficient oxygen for the whole system. The O2 level is in the range of 4-5 mg/l oxygen in the filter circuit (before and about 2 h after urea supplement).
	• We have improved the lighting program so that 100 different intensities can be tested. This will be important, because the light intensity needs to be adjusted to match the increasing cell density (algal growth is the prerequisite of oxygen production).
	• Construction of the flight unit was completed this year and testing is ongoing in preparation for a March 2017 launch.
	• Refined the computer simulation model by obtaining and incorporating more data from the laboratory studies of the CROP system.
	• Minimize the gas leak rate from the laboratory system.
	Test integrated automated Eu:CROPIS system.
