Task Description:	POSTDOCTORAL FELLOWSHIP Astronauts exposed to long periods of unloading due to extended spaceflight experience on average a decrease in bone strength at 2.0 - 2.5% per month. This sharp decline in bone strength can predispose astronauts to fragility fractures, especially when re-entering a gravity-based loading environment due to extra-vehicular activities, extraterrestrial exploration, off-nominal spacecraft landings, and or upon return to Earth. While emerging evidence suggests that unloading, as would occur in microgravity during spaceflight, impairs fracture healing, the cellular and molecular mechanisms by which this occurs largely remains unknown due to a lack of ground-based rodent analog models mimicking spaceflight conditions. Understanding the mechanisms underlying the microgravity-induced impairment in bone regeneration following fracture will lead to the development of new countermeasure targets. One potential countermeasure target is Connexin 43 (Cx43), the primary gap junction protein in bone. Gap junctions facilitate intercellular communication between neighboring bone cells such as osteoblasts and osteocytes and have been strongly implicated in bone fracture healing and bone adaptation to the mechanical environment. In order to study how the duration of microgravity and Cx43 affect fracture healing, will be developed and characterized. This model will be created by combining the ground-based microgravity analog, hindlimb tail unloading, in conjunction with an established mouse endochondral bone healing model, the stabilized open surgical femoral fracture model. Bone healing outcomes via molecular, histological, mechanical and cellular techniques, will be evaluated in wildtype and Cx43 transgenic mice. Biomarker characterization of healing progression will be evaluated. The outcomes of this research will provide better mechanistic insight into how microgravity and gravitational reloading such as that found during spaceflight and terrestrial exploration, respectively, affects bone healing. Further
Rationale for HRP Directed Research	1:
Research Impact/Earth Benefits:	The outcomes of both of these research aims will provide better mechanistic insight into how microgravity and gravitational reloading such as that found during spaceflight and terrestrial exploration, respectively, affects bone healing. Furthermore, it can be used to inform clinical treatment strategies on Earth in fracture patients experiencing bone and muscle loss due to extended bedrest, paralysis, or tumor resection. So far, we have demonstrated that simulated microgravity exposure leads to bone and muscle degradation and impairs fracture healing. However, weight-bearing reambulation (gravitational reloading) following simulated microgravity exposure can improve fracture healing by increasing cartilage and bone formation. Therefore, mechanical loading following disuse, as would occur with spaceflight, extended bedrest, and natural aging has the potential to improve bone repair. However, many individuals suffering from disuse-induced bone and muscle loss, such as found during spaceflight, may have difficulties exercising the injured limb due to locomotor impairments from pain, paralysis, or cardiovascular complications. Therefore, this proposal will identify whether possible therapeutic treatment strategies targeting Cx43, and or other biological targets, is an efficacious approach to augment bone healing during spaceflight conditions.
Task Progress:	 Astronauts exposed to long periods of unloading due to extended spaceflight experience on average a decrease in bone strength at 2.0 - 2.5% per month. This sharp decline in bone strength can predispose astronauts to fragility fractures, especially when re-entering a gravity-based loading environment due to extravehicular activities, extraterrestrial exploration, off-nominal spacecraft landings, and/or upon return to Earth. While emerging evidence suggests that unloading, as would occur in microgravity during spaceflight, impairs fracture healing, the cellular and molecular mechanisms by which this occurs largely remain unknown due to a lack of ground-based rodent analog models mimicking spaceflight conditions. Understanding the mechanisms underlying the microgravity-induced impairment in bone regeneration following fracture will lead to the development of new countermeasure targets. One potential countermeasure targets is Conexin 43 (Cx43), the primary gap junction protein in bone. Gap junctions facilitate intercellular communication between neighboring bone cells such as osteoblasts and osteocytes and have been strongly implicated in bone fracture healing and bone adaptation to the mechanical environment. In order to study how the duration of microgravity and Cx43 affect fracture healing will be developed and characterized. This model will be created by combining the ground-based microgravity analog, hindlimb tail unloading, in conjunction with an established mouse endochondral bone-healing model. He stabilized open surgical fernoral fracture model. Bone-healing outcomes via molecular, histological, mechanistic insight into how microgravity and gravitational reloading, such as that found during spaceflight and terrestrial exploration respectively, affects bone healing. Furthermore, this proposal will identify whether possible treatment strategies targeting Cx43, and/or other biological targets, is an efficacious approach to augment bone healing during microgravity. Characterization of

	mechanosensation, and/or regeneration, using our newly developed fracture healing model of bone unloading. Biomarkers will be assayed via high throughput functional gene expression modalities and correlated to fracture healing progression. Special attention to biological processes implicated in bone pathologies associated with disuse and aging, such as angiogenesis, oxidative stress, senescence, autophagy, wingless/integrated (WNT) signaling, and inflammation, will be assessed via callus gene expression during mechanical unloading and reambulation during the early stages of fracture repair. This will increase our knowledge of putative molecular targets for augmenting bone mass and fracture healing during prolonged unloading found during spaceflight. Furthermore, the role of Cx43 in mature osteoblasts and osteocytes using a transgenic mouse model (DMP1-Cre CX43 fl/fl) will be utilized to assess the role of bone targeted Cx43, as a potential countermeasure, in alleviating disuse and fracture healing associated with bone formation impairments during spaceflight.
