Performance Goal No.:			
Performance Goal Text:			
Task Description:	Anecdotal and empirical findings collected in space and other extreme environments continue to highlight the potential for psychological symptoms and conditions to degrade crew performance, increase conflict, and jeopardize mission success. Indeed, 'negative reactions' during periods of isolation, confinement, demanding work schedules, stimulus reduction, separation from loved ones, sleep deprivation, and a host of other stressors are more appropriately viewed as normative rather than pathogenic. Selection methods and countermeasures serve to mitigate some degree of psychological risk, but long-duration space flight will substantially extend exposure to these and other stressors. Previous research documenting psychological symptoms experienced during space flight and in other isolated and confined environments (ICE) provides evidence of a wide range of psychological and behavioral reactions. Unfortunately however, these collective data ultimately serve to raise more questions than answers. Differences in collection methods, types of symptoms/reactions assessed, psychological constructs examined, and timing and duration of measurements limit conclusions that can be drawn from this research. As a result, understanding of the discrete symptoms and conditions most likely to occur during space flight and in toty quantify the magnitude, probability, or consequences of such risk remains inadequate. The current project proposes to address these notable gaps in knowledge via three specific Aims. First, we will conduct extensive scientific literature reviews and interviews with subject matter experts in order to synthesize existing knowledge of the psychological and behavioral symptoms experienced in space and other extreme environments (Aim 1). Our review will directly inform the development of a comprehensive checklist of symptoms to be monitored among 6 separate cohorts (i.e., 2 Antarctic and 4 Human Exploration Research Analog (HERA) cohorts)) as part of a longitudinal investigation (Aim 2). Symptoms will be examined		
Rationale for HRP Directed Research:			
Research Impact/Earth Benefits:	Anecdotal and empirical findings collected in space and other extreme environments continue to highlight the potential for psychological symptoms and conditions to degrade crew performance, increase conflict, and jeopardize mission success. Indeed, 'negative reactions' during periods of isolation, confinement, demanding work schedules, stimulus reduction, separation from loved ones, sleep deprivation, and a host of other stressors are more appropriately viewed as normative rather than pathogenic. Selection methods and countermeasures serve to mitigate some degree of psychological risk, but long-duration space flight will substantially extend exposure to these and other stressors. Previous research documenting psychological symptoms experienced during space flight and in other isolated and confined environments (ICE) provides evidence of a wide range of psychological and behavioral reactions. Unfortunately however, these collective data ultimately serve to raise more questions than and and duration of measurements limit conclusions that can be drawn from this research. As a result, understanding of the discrete symptoms and conditions most likely to occur during space flight and thus, ability to quantify the magnitude, probability, or consequences of such risk remains inadequate. Thus, there is a need to (1) lidentify the psychological/behavioral symptoms stude to performance; (2) provide accurate and acceptable risk thresholds; (3) inform screening and selection processes; (4) guide further development of suitable working practices (standard operating procedures); and (5) develop interventions and counter measures to mitigate these risks. This project specifically addresses several knowledge gaps related to Risks of Adverse Behavioral Conditions and Psychiatric Disorders [Ed. note: August 2021–Gaps have changed since this grant was awarded in FY2015; see Human Research Roadma https://jliculuting: Gap 1 (Need to identify and quantify the key threats to and prometers of mission relevant behavioral health and perf		

Task Progress:	All project Alms have been met. We developed a 25-tem self-report Mental Health Checkist (MHCL) to assess psychological health in isolated confined extreme (ICE) settings. The MHCL includes three reliable subscales—positive adaptation, poor self-regulation, and anxious apprehension—each assessing unique aspects of psychological health. In a 9-month longitudinal study, we assessed 110 personnel stationed at either McMurdo (coastal station) or South Pole (inland station). At the South Pole station, a total of 22 participants were enrolled and 88 participants were enrolled at the McMurdo station. Because crew at McMurdo are not required to be on station for the entire winter season, there was variability in the number of monthly sessions completed at this station. Antarctic participants were predominantly White (94.5%, n = 104) males (80%, n = 88) between the ages of 22 and 70 years old (M = 37.63, SD = 11.95). Because the greatest number of McMurdo participants completed 6 months of assessments, this time point was used to compare monthly outcomes across the two stations. For all participants, MHCL positive adaptation scores decreased significantly and MHCL poor self-regulation scores increased significantly from baseline to the end of study. Overall change in MHCL anxious apprehension scores across were observed at McMurdo compared to the South Pole during the early months of the mission. Anxious apprehension scores were significantly higher at the McMurdo station than at South Pole during all months. Prevalence and severity of physical symptoms increased significantly from baseline to the end of study in the full Antarctic sample but there were no significant differences in physical symptoms between the two stations. Changes in biomarkers of stress (cortisol, DHEA, or the cortisol:DHEA ratios) were not observed from baseline to the end of the mission. However, cortisol and cortisol:DHEA ratios were significantly higher among McMurdo compared to South Pole participants. Cognitive Assessment Tool for Windows (Win
	Several study participants underwent emergency evacuation from the McMurdo station during the study. We examined monthly reports, biomarkers, and cognitive performance among 4 evacuees compared to the remaining McMurdo sample ($n = 84$) to identify potential indicators of distress prior to evacuation. Emergency evacuation occurred for medical reasons ($n = 2$) or for psychiatric reasons ($n = 2$). Elevated MHCL anxious apprehension scores were most common among all evacuees. Elevated physical symptoms were also apparent in one psychiatric and one medical evacuee in the months prior to evacuation. We did not find any biomarker of stress or objective sleep regularity to differ among evacuees compared to the full sample.
	At the Palmer station, the MHCL measure was administered to 26 participants during two winter-over seasons. MHCL data were collected for 4 consecutive months. The Palmer station is similar to the McMurdo station in climate and its coastal location, but similar to the South Pole in terms of size/number of residents. Similar to Antarctic participants at the McMurdo and South Pole stations, positive adaptation scores declined across mission whereas changes in poor self-regulation were more modest. The greatest increases in anxious apprehension scores were observed in later mission months.
	Collective findings indicate the MHCL is a reliable and useful measure for assessing psychological risk in ICE settings. Each of the MHCL scales contributes unique information in this regard, particularly when combined with assessment of physical complaints.
