Performance Goal Text:		

Rationale for HRP Directed Research:This research is directed because it contains highly constrained research, which requires focused and constrained data gathering and analysis that is more appropriately obtained through a non-competitive proposal.Research Impact/Earth Benefits:The primary intent of this activity is to create an operational benefit for crewmember exercise prescriptions. The techniques used to collect and assess data are those typically used during Earth-based evaluations. There are no direct benefits to life on Earth, but there are substantial benefits for crewmembers.As of July 14, 2011, 9 crewmembers have consented to participate in the evaluation, and 8 baseline data collection (BDC) sessions have occurred. BDC sessions include procedure training for the inflight portion of the investigation, and biomechanical data collection. During the biomechanical data collection, motion capture and ground reaction force data are collected as each subjects walks and runs on a force-measuring treadmill. Data are collected as each subjects perform both a walking and a running trial. Trial duration is 15 seconds. Before each data collection session, the crewmember and investigator discuss the probable exercise program to be used on the ISS to determine if the maximum testing speed should be decreased. Motion capture data are collected by a 12 camera motion capture system at 250 Hz, and ground reaction force data are collected by dual force plates built into the treadmill at 1000 Hz. Data are collected simultaneously by a single workstation. To date, none of the processing of the BDC data has been completed for any crewmembers.Task Progress:Three crewmembers have completed infight data collection includes standard hi-definition videography and ground reaction force recording. Ground reaction force data are collected by dual force plates built into the treadmill	Task Description:	There are many factors that may contribute to the deconditioning that occurs during long-term microgravity exposure. Countermeasures hardware limitations, suboptimal exercise programming, and alterations in gait biomechanics may all contribute to physiological losses. During the NASA International Space Station Exercise Prescription Workshop in October 2008, internal and external experts identified a need to better quantify specific physiological responses to exercise in microgravity. Knowledge of resistance exercise biomechanics while on ISS will provide insight as to why bone, muscle and cardiovascular health are lost during long duration spaceflight. There have been no rigorous evaluations of locomotion biomechanics during exercise in microgravity on the ISS. The installation of the Second-Generation Treadmill (T2) on the ISS will allow the measurement of ground reaction forces (GRF) during exercise. Quantification of these forces is vital to understanding the musculoskeletal benefits of treadmill exercise. GRF data used in combination of joint motion data obtained from video can be used to quantify the joint torques that occur during exercise, which will give critical information regarding exercise efficacy. It is probable that variables such as speed, external load (EL) applied to the waist-shoulder harness, and vibration-isolation affect locomotive biomechanics, which could influence exercise prescription efficacy. The objective of this evaluation is to collect biomechanical data from crewmembers during treadmill exercise. Up to 6 crewmembers will be assessed during nominal exercise sessions on the T2 during long duration ISS mission. Data will be collected from up to 6 sessions per crew member, space approximately 30 days apart. Video data will be collected using a standard high-definition video camera, and GRF data will be collected fireetly from the T2. Data will be downlinked from ISS for post processing. Video will be digitized and joint position throughout exercises will be determined using a two-di
Research Impact/Earth Benefits: techniques used to collect and assess data are those typically used during Earth-based evaluations. There are no direct benefits to life on Earth, but there are substantial benefits for crewmembers. As of July 14, 2011, 9 crewmembers have consented to participate in the evaluation, and 8 baseline data collection (BDC) sessions have occurred. BDC sessions include procedure training for the inflight portion of the investigation, and biomechanical data collection. During the biomechanical data collection, motion capture and ground reaction force data are collected as each subject walks and runs on a force-measuring treadmill. Data are collected at speeds or 5.0 and greater. At 4.5 mph, subjects perform both a walking and a running trial. Trial duration is 15 seconds. Before each data collection session, the crewmember and investigator discuss the probable exercise program to be used on the ISS to determine if the maximum testing speed should be decreased. Task Progress: Task or collected by all force plates built into the treadmill at 1000 Hz. Data are collected for any crewmembers. Three crewmembers have completed one of six sessions. One crewmember has completed three of six total sessions, and two crewmembers have completed one of six sessions. Inflight data collection includes standard hi-definition videography and ground reaction force each care collected by the treadmill as part of standard exercise data collection. The first two sessions for each crewmember are monitored in real time at the TeleScience Center at JSC Mission Control. After each session, video and treadmill data are downlinked and collected by the PI. To date, inflight video has been examined for integrity, but has not been processed.
