Task Description:Herein and the second an	urrent space packaging. im B. To complete a risk-benefit analysis on the usage of the space environment for cold food storage. im C. To provide recommendations as to the formulation changes, processes, packages, and environments for each pace food product that would result in a five-year shelf life for that product. im D. To identify the technology needs associated with implementing any of the aforementioned integration ecommendations. at the study conclusion, a course to shift the space food produets to a five-year shelf life will be proposed. Overall system or category changes will be clearly identified, and products with little chance of meeting the five-year shelf life urdle will be delineated for replacement or removal from long duration menus. The required future work to deliver this ostulated integration for the food system will be identified. This research is directed because it contains highly constrained research, which requires focused and constrained data athering and analysis that is more appropriately obtained through a non-competitive proposal. The implications of the study go beyond future space missions in that successful optimization would raise the food uality and simplify food logistics for International Space Station provisions and for food rations used terrestrially for life efforts and military applications. The Integration of Product, Package, Process, and Environment: A Food System Optimization seeks to optimize food rocus sing technologies, and modified storage conditions. The first review ascenduced to identify packaging technologies that out due would in place of the current packaging system to repeakaged space foods. This study began with two literature reviews. The first review and low optical density, seem especially viable as a ackaging material replacement. Mostiure seavengers, which are widely available commercially, are not currently used the food system, and may be exceptionally useful for products that are very sensitive to moisture. Other technologies,

A no es	utrition or poor food intake decreases with implementation of this integrated food system. Ience, The Integration of Product, Package, Process, and Environment: A Food System Optimization seeks to optimize bod product shelf life for the space food system through product recipe adjustments, application of new packaging and rocessing technologies, and modified storage conditions. Specifically, the research aims are: Aim A. To summarize the vailable packaged food technologies that would offer significant barrier or antioxidant property improvements over
Oj ex ina ac ma de vit	he viability of all extended duration missions. potimizing the food system to achieve a five-year shelf life mitigates the risk of inadequate food system during xtended missions. Two causes of an inadequate food system are inadequate nutritional content within the food and hadequate acceptability of the food leading to insufficient intake. This study directly addresses those nutrition and cceptability concerns. Nutritional content and food quality, particularly as products age, are indicative of the food hatrix, history, and storage environment. For example, a high availability of oxygen in a food package can be etrimental to product shelf life. The oxidative reactions that cause rancidity also lead to the degradation of vitamin C, itamin A, folic acid, and thiamin (Gregory 1985: Gregory JF. 1985. Chemical changes of vitamins during food rocessing. In: Richardson T and Finley JW, editors. Chemical Changes in Food During Processing. Westport (CT): VI Publishing Company, 373-408). Likewise, a product subjected to high heat in processing may undergo onenzymatic browning, but broad vitamin degradation should also be expected after thermal processing. By stablishing the proper recipe, process, package, and storage condition, the product is better positioned to sustain utrition and acceptability over the product life. The chances of performance decrement or illness due to insufficient
